CASE REPORT

Presentation of Gall Stone Ileus as Gut Obstruction

INTRODUCTION

Gallstone ileus is a rare complication of cholelithiasis. It has a propensity to affect females and accounts for less than 0.5% of cases of mechanical small bowel obstruction.1-2 It occurs when gallstone enters the small bowel through a biliary enteric fistula, with more than half of these being cholecystoduodenal fistulas. This fistula is created as the gallstone exerts pressure against the biliary wall, leading to necrosis of GB wall.3 A bowel obstructions then occurs if the newly entered gallstone is of sufficient size, usually greater than 2 cm.4 The ileum is the narrowest part of the bowel and is thus the area affected in the majority of cases.2,3

Clinically, gallstone ileus presents as an episodic bowel obstruction with diffuse abdominal pain and vomiting. Interval improvement in symptoms may occur as the stone becomes dislodged, with symptoms recurring as the stone becomes repeatedly obstructed.5 Contrast Tomography is most often used in the investigation of gallstone ileus,6-9 as only a minority of gallstones have sufficient calcium content to be visible on abdominal X-ray.6,9 Management of gallstone ileus is predominantly surgical, usually involving an enterolithotomy with or without additional procedures.

A 56-year-old female presented to the emergency department of SKIMS, Srinagar as a referral case with chief complaint of abdominal pain and vomiting. A CT scan was performed and showed an evolving bowel obstruction with features of gut ischemia with pneumobilia although no frank hyper density suggestive of a gallstone was noted. The patient underwent emergency surgery and a 60 mm obstructing calculus was removed from the patient’s jejunum, with a formal tube cholecystostomy. JMS 2018; 21(2):117-119

ABSTRACT

Gallstone ileus is an uncommon and often life-threatening complication of cholelithiasis. In this case report, we discuss a difficult diagnostic case of gallstone ileus presenting as small gut obstruction with ischaemia. A 56-year-old female presented with abdominal pain and vomiting. A CT scan was performed and showed an evolving bowel obstruction with features of gut ischemia with pneumobilia although no frank hyper density suggestive of a gallstone was noted. The patient underwent emergency surgery and a 60 mm obstructing calculus was removed from the patient’s jejunum, with a formal tube cholecystostomy. JMS 2018; 21(2):117-119
hospital and was discharged a six days later to a regional hospital for rehabilitation.

**DISCUSSION**

This case represents what was initially a missed diagnosis of gallstone ileus due to a non-calcified gallstone. The pneumobilia was at first reported as being due to a previous sphincterotomy. The diagnosis of gallstone ileus was made later only after exploration.

The CT findings of gallstone ileus include thickening of the gallbladder wall, pneumobilia and bowel obstruction with obstructing gallstones.\[^{6-8}\] However, gallstones may be missed on CT as they are not always hyperdense.\[^{9,10}\] In one study, low density stones accounted for around 3% of gallstones.\[^{9}\] In this case, gas was appreciated within the thick walled gall bladder and in intrahepatic biliary radicals. This is a well-documented sign of gallstones in the literature.\[^{11}\] In addition to this duodenum was thick walled and no cholecystoduodenal fistula could be seen on CT.

Management of gallstone ileus involves removal of the obstructing stone leading to resolution of the bowel obstruction. This is achieved through either a laparoscopic or open enterolithotomy. It is not uncommon for a bowel resection to be required if surgical complications such as perforation or difficult stone retrieval occur.\[^{5}\] A definitive procedure to treat the cause of the ileus, such as a cholecystectomy or fistula closure is also often required, to reduce other complications such as recurrence or cholecystitis.\[^{5}\] This procedure can often be performed at the same time as an enterolithotomy in low-risk patients.\[^{2,12,13}\] Higher risk patients, such as in the case discussed, may undergo enterolithotomy without an additional procedure as fistulas may close or reduce in size without subsequent intervention.\[^{14,15}\]
Gallstone ileus remains an important diagnosis as it results in significant morbidity and mortality. The mortality rate remains high at around 5–7%.[14,16] Furthermore, the mortality rate is 5 to 10 times higher than other mechanical causes of small bowel obstruction. Recurrent gallstone ileus occurs in a significant minority of patients treated with enterolithotomy alone, and more than half of these occur in the first 6 months following surgery.[14]

This case emphasizes the importance in considering gallstone ileus as a cause for a mechanical bowel obstruction. It demonstrates a difficult diagnostic case of gallstone ileus with no evidence of calcification or increased density on CT that would be suggestive of an obstructing gallstone. The radiological diagnosis of gallstone ileus certainly changed management immediately and may have saved this frail patient. Difficulty in diagnosis was further compounded by conflicting physical examination findings with a seemingly inconclusive abdominal ultrasound study. There is a need for careful consideration of clinical history in conjunction with other radiological signs such as pneumobilia or bowel obstruction to establish a diagnosis of gallstone ileus.
